## 1 Antiderivative

### 1.1 Definition of antiderivative

**Definition 1.** Let  $f$  and  $F$  be functions defined on the interval  $\mathcal{J}$ . Function  $F$  is *antiderivative* to the function  $f$  on  $\mathcal{J}$ , if, for each  $x \in \mathcal{J}$ ,  $F'(x) = f(x)$ . If the interval  $\mathcal{J}$  contains some of its endpoints, then at this endpoint we consider the corresponding one sided derivative.

### 1.2 Existence of antiderivative

**Theorem 2.** Let  $f$  be continuous on interval  $\mathcal{J}$ , then it has an antiderivative  $F$  on  $\mathcal{J}$ .

This theorem has a simple corollary.

**Corollary 3.** If  $f$  is an elementary function defined on interval  $\mathcal{J}$ , then it has an antiderivative  $F$  on  $\mathcal{J}$ .

### 1.3 Indefinite integral

**Theorem 4.** Let  $F$  be an antiderivative to  $f$  on interval  $\mathcal{J}$ . Then a function  $G$ ,  $G(x) = F(x) + C$ ,  $x \in \mathcal{J}$ , where  $C \in \mathbb{R}$  is a constant, is also an antiderivative to  $f$  on interval  $\mathcal{J}$ .

**Theorem 5.** Let functions  $F$  and  $G$  be antiderivatives to  $f$  on interval  $\mathcal{J}$ . Then there exists a constant  $C \in \mathbb{R}$  such that, for any  $x \in \mathcal{J}$ ,  $G(x) = F(x) + C$ .

**Definition 6** (Indefinite integral). The set of all antiderivatives to  $f$  on interval  $\mathcal{J}$  is called *indefinite integral* of function  $f$  on interval  $\mathcal{J}$ . We use the notation

$$\int f(x) dx = F(x) + C,$$

where the symbol  $dx$  indicates that  $x$  is a variable in the function  $f$ ,  $F(x)$  is one of *antiderivatives* to  $f(x)$  on  $\mathcal{J}$  and  $C \in \mathbb{R}$  is an *arbitrary constant*.

## 2 Computing indefinite integrals

### 2.1 Rules for integration

**Theorem 7.** Let functions  $f$ ,  $g$  have antiderivatives on  $\mathcal{J}$ . Then functions  $(f + g)$ ,  $(f - g)$  and  $cf$ ,  $c \in \mathbb{R}$ , have also antiderivatives on  $\mathcal{J}$  and

$$\begin{aligned}\int (f(x) + g(x)) dx &= \int f(x) dx + \int g(x) dx, \\ \int (f(x) - g(x)) dx &= \int f(x) dx - \int g(x) dx, \\ \int cf(x) dx &= c \int f(x) dx.\end{aligned}$$

**Important!**

There are no rules for products, quotients or composite functions.

### 2.2 Method of direct integration

We use only basic formulae, rules for integration and manipulation with expressions.

### 2.3 Method of integration by parts

**Theorem 8** (Integration by parts). Let functions  $u$  and  $v$  have continuous derivatives  $u'$  and  $v'$ , respectively, on interval  $\mathcal{J}$ . Then

$$\int u(x)v'(x) dx = u(x)v(x) - \int u'(x)v(x) dx.$$

### 2.4 Change of variables

**Theorem 9** (Change of variables). Let function  $f$  be continuous on interval  $\mathcal{I}$  and  $F$  be its antiderivative on  $\mathcal{I}$ . Moreover, assume that function  $g$  has the first derivative  $g'(x)$  at each point  $x \in \mathcal{J}$  and  $g(x) \in \mathcal{I}$  for any  $x \in \mathcal{J}$ . Then the composite function  $F(g(x))$  is an antiderivative to  $f(g(x))g'(x)$  on interval  $\mathcal{J}$ .
